COVID-19 INFECTION AMONG ONTARIO WORKERS

BETWEEN FEBRUARY 2020 AND DECEMBER 2021

Key Insights

- The risk of COVID-19 among Ontario workers varies by occupation. Identifying groups with the highest risks can provide a better understanding of where prevention efforts are needed to reduce disease transmission.
- The risk of COVID-19 varies by region. Workers living in densely populated regions had a higher risk of COVID-19 infection, which may reflect background community risks.

Occupations with higher risk of COVID-19 infection

in comparison to other occupations

Transport Workers

Medical Lab Technicians/ Technologists

Nurses

Textile Fabrication Workers

Food and Beverage Processing Workers

Personal Services Workers

Emergency Services Workers

Janitors and Cleaners

1

Higher risk of COVID-19 infection may be due to indoor, in-person operations, with close physical proximity and frequent contact with others.

Lower risk of COVID-19 infection may be due to outdoor work, well-ventilated environments, use of respiratory protection, and minimal physical proximity and contact with others (e.g. remote work).

Risk of COVID-19 infection by workers' region of residence

in comparison to workers living in other regions

Workers living in **Toronto**:

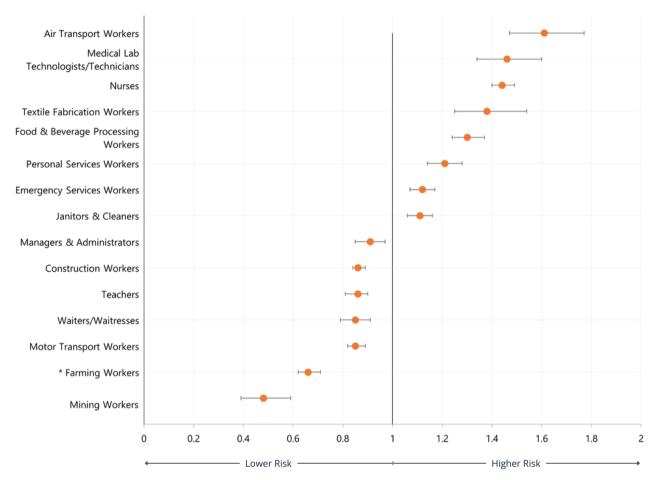

Workers living in the Central East Region (Durham, Peel, and York):

Risk of COVID-19 infection by occupation

in comparison to other occupations

Hazard Ratio† (HR) and 95% Confidence Intervals

About the Data

This fact sheet summarizes the risks of COVID-19 infection among workers in the Occupational Disease Surveillance System (ODSS) by occupation and region, in comparison to all other workers in the ODSS.

For more information on the project, visit:

* www.occupationalcancer.ca/project/covid-19-surveillance/

[†] The hazard ratio (HR) is a measure used to compare the risk of an event (e.g. COVID-19 infection) in one group (Group A) compared to another group (Group B). If the risk of COVID-19 infection is higher in Group A than Group B, the hazard ratio will be above 1; if the risk is lower in Group A than Group B, the hazard ratio will be below 1; and if the risk is approximately equal in Group A and B, then the hazard ratio will equal 1.

 $^{{\}rm *Risk\ estimates\ among\ farming\ workers\ may\ not\ fully\ capture\ COVID-19\ infections\ among\ migrant\ workers.}$
